MTF Clinical Dossier
STUDY OBJECTIVE

To compare clinical outcomes and revision rates for anterior cruciate ligament (ACL) reconstructions using bone-patellar tendon-bone (BPTB) allografts versus BPTB autografts in a population of patients aged 25 years and younger.

METHODS

- 81 patients were enrolled (28 allografts and 53 autografts)
- Patients were given the choice between allograft and autograft
- All Allografts were sourced by MTF
- Minimum follow-up was 24 months

RESULTS

- The allograft group showed a 7.1% failure rate and autograft showed a 9.4% failure rate
- Using a patient-choice ACL graft selection program after appropriate counseling and using graft specific rehabilitation programs, not chemically processed or irradiated BPTB allograft reconstructions have no greater failure rate than autografts in patients aged 25 years and younger at a minimum 2-year follow-up
**STUDY OBJECTIVE**

To prospectively compare outcomes of primary anterior cruciate ligament (ACL) reconstruction with either Achilles tendon allograft with soft-tissue fixation or standard bone patellar tendon–bone autograft with interference screw fixation.

**METHODS**

- 159 patients (41 allografts, 118 autografts) were included in the study
- Patients were evaluated preoperatively and postoperatively at 1 to 2 weeks, 6 weeks, 3 months, 6 months, and then annually for 5 years
- All Allografts were sourced by MTF

**RESULTS**

- At five-year follow-up both groups achieved similar long-term outcomes
- Allograft patients reported less pain than autograft patients at 1 and 6 weeks after surgery
- Allograft patients reported better function than autograft patients at 1 week, 3 months, and 1 year, and fewer activity limitations throughout the follow-up period
STUDY OBJECTIVE

This study was performed to determine the failure rate of patients undergoing primary anterior cruciate ligament (ACL) reconstruction with an Achilles tendon allograft by a single surgeon with the same surgical technique, graft fixation, and postoperative rehabilitation. The Achilles tendon allograft was obtained from a single source.

METHODS

• 144 patients were followed up at a mean of 40 months and a minimum of 24 months
• The results of those 144 allograft patients were compared against historic autograft results as a control
• Evaluation included a questionnaire at serial follow-up visits, physical examination, and return to play
• All Allografts were sourced by MTF

RESULTS

• The failure rate for Allograft was 5.6%. This is comparable to historic autograft failure rates which range from 5%-13%
• A $X^2$ contingency test was performed comparing patients aged 25 years or younger and those aged over 25 years with a resulting P value of 0.5811. No statistically significant difference between the groups of failures was seen
STUDY OBJECTIVE

To compare the outcomes of a consecutive series of non revision bone–patellar tendon–bone (BPTB) allograft anterior cruciate ligament (ACL) reconstructions in patients aged 40 years or older and patients aged younger than 40 years.

METHODS

- 32 patients were followed up at a mean of 40 months and a minimum of 24 months
- Preoperative and postoperative outcome assessments included Cincinnati, Lysholm, and Tegner scores and International Knee Documentation Committee (IKDC) activity scores. Lachman test, pivot-shift test, and KT arthrometer (MEDmetric, San Diego, CA) measurements were obtained at a minimum of 24 months after surgery

RESULTS

- The outcomes of BPTB allograft ACL reconstructions were not different both subjectively and objectively for patients aged 40 years or older and patients aged younger than 40 years. BPTB allograft ACL reconstruction provides consistent results for patients of all age groups
STUDY OBJECTIVE

The purpose of this study was to compare infection rates between procedures using allograft or autograft tissue in primary anterior cruciate ligament (ACL) reconstruction.

METHODS

- 221 autograft patients and 640 allograft patients were included in this study
- A combined prospective and retrospective multicenter cohort study was performed over a three-year period
- Graft selection was determined by the individual surgeon
- Inclusion and exclusion criteria were equivalent for the two groups (allograft and autograft tissue)

Our primary outcome was intra-articular infection following anterior cruciate ligament reconstruction.

RESULTS

- The rate of superficial infections in the entire study group was 2.32%. We did not identify a significant difference in the rate of superficial infections between autograft and allograft reconstruction in our study group
- While the theoretical risk of disease transmission inherent with allograft tissue cannot be eliminated, we found no increased clinical risk of infection with the use of allograft tissue compared with autologous tissue for primary anterior cruciate ligament reconstruction
Anterior Laxity, Slippage, and Recovery of Function in the First Year After Tibialis Allograft Anterior Cruciate Ligament Reconstruction

Title: Anterior Laxity, Slippage, and Recovery of Function in the First Year After Tibialis Allograft Anterior Cruciate Ligament Reconstruction

Author: Conrad K. Smith, PhD, Stephen M. Howell, MD, and Maury L. Hull, PhD

Key Takeaways: There was no increase in anterior laxity or slippage at 1 year when using MTF allograft

STUDY OBJECTIVE

When slippage-resistant fixation is used with a soft tissue graft, early recovery of function does not result in a clinically important increase in anterior laxity and slippage.

METHODS

- Nineteen subjects were treated with a single-tunnel, single-looped, MTF tibialis allograft with slippage-resistant, cortical fixation
- An examiner, different from the treating surgeon, used stereophotogrammetric analysis to compute the increase in anterior laxity at a 150 N anterior force and slippage between the day of surgery and each monthly follow-up interval, and determined recovery of function and motion

RESULTS

- Early recovery of function after ACL reconstruction with an MTF soft tissue allograft did not result in a clinically important increase in anterior laxity and slippage at 1 year
STUDY OBJECTIVE

The purpose of this study was to compare revision rates of Allograft and Autograft to see if autograft would result in decreased failure rates 2 years after revision ACL reconstruction.

METHODS

- 1205 patients were enrolled in the study; half of the patients received an autograft and half received an allograft for their reconstruction. All surgeries were performed by members of the AOSSM
- The study used only MTF tissue and all patients were followed up with at 2 years post operation

RESULTS

- The Autograft group had a 97.8% Success rate (520 out of 542)
- The Allograft group had a 95.6% Success rate (516 out of 540)
